OPIOID-RELATED HARMS Risks by occupation among Ontario workers who had a work-related injury

This study examined the risk of opioid-related harms by occupation among 1.7 million Ontario workers who had a work-related injury or illness. Workers in various occupational groups were compared to all other workers.

Workers in the following broad occupational groups had higher risks of both opioid-related poisonings and mental & behavioural disorders:

Forestry and logging

Processing (mineral, metal, chemical)

Construction and trades

Processing (food, wood, textile)

Materials handling

Workers in other occupational groups had a higher risk of only one of the harms:

Workers in transport equipment operating had a higher risk of **poisonings**.

Workers in mining and **quarrying** had a higher risk of mental & behavioural disorders.

However, results were not always consistent within some of these broad occupational groups. In fact, workers in certain specific occupations within these groups had lower risks of experiencing opioid-related harms.

Workers in other specific machining and transport occupations, namely wood and other machining, and rail and other transport, did not have either an increased or decreased risk of harm.

For other broad occupational groups (service, medicine & health, clerical, sales), no association was seen with opioid-related harms. However, for workers in specific occupations within these groups, higher risks of harms were observed:

Key message: Results provide additional evidence that certain occupational groups are most affected by opioid-related harms. Although further research is needed to understand the specific workplace risk factors involved, findings point to subgroups of the workforce where prevention and harm reduction efforts should be targeted to reduce opioid-related harms.
